BACKGROUND

In a recent clinical trial (ACTG 5257) no difference in virologic failure of a cART containing atazanavir/r (ATV/r) or darunavir/r (DRV/r) was found

For the endpoint of discontinuation because of intolerance, the regimen with DRV/r was superior to that of ATV/r (49% of the stops of ATV/r were attributed to jaundice or hyperbilirubinemia)

These and other intolerances to ATV/r remain a concern for clinicians who are considering to initiate treatment with a regimen including ATV/r

OBJECTIVE

To adopt the analysis plan used in ACTG 5257 to gather further information on the comparison ATV/r vs. DRV/r with longer follow-up in people seen for care in the observational setting

PATIENTS AND METHODS

Participants in the Icona Foundation Study who started cART with 2NRTI+ ATV/r or DRV/r while ART-naïve were included

Several endpoints were evaluated, similar to those defined in ACTG 5257:

1. A confirmed VF>200 copies/mL after 6 months of therapy
2. A discontinuation of DRV/r or ATV/r for any reasons
3. A discontinuation of DRV/r or ATV/r because of intolerance/toxicity (as reported by the treating physician)
4. The composite endpoint of VF or discontinuation of DRV/r or ATV/r

Statistical analysis

Survival analysis with Kaplan-Meier curves and Cox regression model stratified by clinical site was used. Participants' follow-up accrued from cART initiation to the date of the event or to the date of last available visit/viral load. The competing risk approach was used to draw the Kaplan-Meier curves of the probability of stopping due to toxicity, with administrative censoring at the last clinical visit for those stopping for other reasons

RESULTS

894 persons in Icona Foundation Study who started 2NRTI+ATV/r and 686 2NRTI+DRV/r when ART-naïve on average in 2011 (IQR:2010-2012) were included. Most common NRTIs used were FTC/TDF (84%) and ABC/3TC (12%). Median age was 40 years, 22% females, 44% heterosexuals. Pts starting ATV/r were more likely to be hepatitis B/C infected (2% and 14% vs, 1% and 9%, p=0.001), they started one year earlier (2011 vs. 2012, p=0.001), were more likely to be enrolled in sites located in the north of Italy (63% vs. 54%, p=0.04), started cART less promptly after HIV diagnosis (5 vs. 2 months, p=0.02) and less likely to have started TDF/FTC (83% vs. 85%, p=0.02, Table 1). Median (IQR) follow-up was 56 weeks (21-104), with 18% (n=91) persons being followed up for longer than the trial duration of 96 weeks

Table 1. Main characteristics according to third drug started

*Chi-square or Kruskal-Wallis test as appropriate

Overall, 330 persons discontinued ATV/r and 181 DRV/r. Figure 1 shows the distribution of reasons for discontinued stratified by third drug, as reported by clinicians. Stops due to gastro-intestinal intolerance/toxicity were similar (6% DRV/r vs. 7% ATV/r)

By 2 years of cART: the rate of pure virological failure was 7.6% (95% CI:5.6-9.6) in the ATV/r and 2.4% (0.9-3.9) in the DRV/r group; 9.8% (7.6-12.0) of those starting ATV/r experienced discontinuation due to intolerance/toxicity vs. 6.5% in DRV/r group (95% CI:4.2-8.8, p=0.04, Figure 2)

Figure 2. Kaplan-Meier estimates

After controlling for several confounders (footnote of Table 3) the relative hazard (RH) of discontinuation due to toxicity for ATV/r vs. DRV/r was 2.01 (95% CI:1.23, 3.28, p=0.005). Of note, this difference remained significant after controlling for current bilirubin level (RH=1.78, p=0.02). There were no statistical differences detected for any of the other outcomes (p≥0.20, Table 3). Contrary to the trial, the rate of viral failure tended to be higher in the ATV/r group; the big difference in the unadjusted analysis was reduced mainly by the adjustment for calendar year, NRTI-pair and mode of transmission

Table 3. Relative hazards from fitting four separate Cox regression models

Outcomes	Crude and adjusted relative hazards			
	Crude RH (95% CI)	p-value	Adjusted* RH (95% CI)	p-value
Discontinuation				
DRV/r	1.00		1.00	
ATV/r	1.18 (0.97, 1.43)	0.09	1.16 (0.92, 1.47)	0.20
Discontinuation due to toxicity				
DRV/r	1.00		1.00	
ATV/r	1.48 (0.98, 2.22)	0.06	2.01 (1.23, 3.28)	0.005
VF>200 copies/mL				
DRV/r	1.00		1.00	
ATV/r	3.49 (1.89, 6.43)	<.001	1.63 (0.75, 3.54)	0.22
VF>200 copies/mL or discontinuation				
DRV/r	1.00		1.00	
ATV/r	1.25 (1.02, 1.52)	0.03	1.14 (0.90, 1.45)	0.27

Adjusted for (age, gender, nation of birth, mode of HIV transmission, hepatitis co-infection status, AIDS diagnosis, nucleoside pair started, baseline CD4 count and viral load and year of starting cART

CONCLUSIONS

Our results seem to be consistent with those of the ACTG 5257, indicating a higher propensity to discontinue ATV/r for reasons due to toxicity

When viral failure, all cause discontinuations and the composite endpoint of treatment failure were considered, there was no difference between ATV/r- and DRV/r-based regimens

We cannot rule out possible bias due to unmeasured confounding or other introduced by the subjective nature of the data reported as the reason for stopping
