Background
Declining rates of hospitalizations for HIV+ occurred shortly after the availability of cART. These shifts were largely attributed to the effects of cART, which, by improving the immune status of HIV-infected persons, decreased the incidence of AIDS events. However, trends in the late cART era are less defined, with some studies suggesting stabilization or increasing rates of hospitalization. This could be due to the occurrence of late presentation, aging of HIV population, development of chronic and organ disease, and toxicity from long-term ART use, development of multi-resistant viruses.

Objectives
To evaluate the trend in hospitalizations rates occurred during 1997-2012 in persons with HIV entering specialized care in Italy. To assess risk factors for hospitalizations.

Materials and Methods
Hospitalization data collection
The primary cause of hospitalization was grouped into 9 diagnostic categories: the main categories were:
• AIDS defining illness (ADI)
• Non-AIDS infections (e.g. pneumonia, endocarditis, meningitis, ...)
• Liver/gastrointestinal diseases (e.g. chronic hepatitis, liver cirrhosis, pancreatitis, ESLD, ...)
• Cardiovascular diseases (e.g. myocardial infarction, coronary heart disease, cerebrovascular disease/stroke, heart failure, ...)
• Non-AIDS cancer (e.g. primary lung cancer, ICC, breast cancer, ...)
The remaining 4 categories included: renal, psychiatric, hematological and other diseases. Each hospitalization was placed into a single mutually exclusive category.

Study population
HIV+ infected patients of the ICONA Foundation Study enrolled during the period 1997-2012.

Inclusion criteria
A hospitalization was included if occurred at least 30 days after the enrollment and was defined as admission to any Italian hospital for two or more days, within 31/12/12.

Statistical Methods
Patients were followed-up from the baseline to a hospitalization or their last visit. Participants could be included in multiple periods and could contribute more than one hospitalization per period. The incidence rate of hospitalization was calculated as the ratio of the number of hospitalizations recorded after baseline divided by PYFU and expressed as rate per 100 PYFU, with 95% confidence intervals (CI).

The number of hospitalizations, PYFU, and rates of hospitalization (per 100 PYFU), due to all causes and within each diagnostic category, were calculated for the study period, and the following priori determined study periods, characterized by availability of different antiretrovirals: 1997-1999; 2000-2005; 2006-2009; 2010-2012. These were defined as early (1997-1999), mainly non-boosted protease inhibitors (PI) and norvirinfine); old generation cART (2006-2009: second generation boosted PI’s and current cART (2010-2012: modern cART including in addition integrase inhibitors-INI and new non nucleoside inhibitors NNI).

Risk factors for hospitalization were assessed by univariable and multivariable Poisson regressions (using PYFU as the offset) by a generalized estimating equation (GEE) model with a sandwich covariance matrix estimator, to account for participants contributing multiple hospitalizations, time dependent factors (i.e. age, CD4 count) were updated for each calendar year.

Results
Overall, during the study period 10,527 participants (25% females; 38% heterosexuals, 31% MSM, 23% IDU; 27% with HCV; median age 36 (IQR 31-42) for a total of 51,281 PYFU, were enrolled. Of these, 1,760 (17%) were hospitalized at least once in any period hospitalization (Table 1).

Conclusions
Hospitalization rates decreased during the period 1997-2012 in ICONA cohort especially in ADI, non AIDS infections and liver/gastrointestinal diagnostic categories; cardiovascular diseases remained unchanged while for non-AIDS cancers a significant increase was observed. Considering age hospitalization for liver/gastrointestinal diseases and cardiovascular diseases were more frequent among patients older than 50 years. These findings are related to a population of persons with HIV on care, and this may limit their generalizability to the overall population of persons living with HIV.
